

What is Flow Cytometry?

Flow cytometry is a technique used to analyze and measure characteristics of cells or particles in a fluid sample. It provides quantitative data about cell populations based on their physical and chemical properties.

Basic Components of a Flow Cytometer

Fluidics System	Controls the flow of the sample through the instrument.
Optics System	Includes lasers, detectors, and filters for detecting and measuring light signals.
Electronics System	Converts optical signals into electronic signals for data analysis.

Data Acquisition and Analysis

Forward Scatter (FSC): Measures the size of particles/cells.

Side Scatter (SSC): Reflects the internal complexity or granularity of particles/cells.

Fluorescence Detectors: Capture emitted light at specific wavelengths from labeled cells.

Compensation: Corrects spectral overlap between fluorochromes to obtain accurate fluorescence measurements.

Gating: Defines specific populations of interest within the sample based on fluorescence intensity and scatter characteristics.

Considerations and Tips:

Choose appropriate fluorochromes and antibodies for specific targets.

Use appropriate controls (positive, negative, compensation) to ensure accurate results.

Maintain instrument performance through regular cleaning, calibration, and quality control.

Optimize staining protocols and instrument settings for best results.

Data analysis software skills are crucial for extracting meaningful information.

Staining and Sample Preparation

Fluorescent Labels: Use fluorescent dyes or antibodies to label specific cell components or markers of interest.

Fixation and Permeabilization: Helps preserve cell structure and allows the entry of antibodies into the cell.

Compensation Controls: Used to correct for spectral overlap between different fluorochromes.

Applications of Flow Cytometry

Immunophenotyping: Identifying and characterizing different cell types in a mixed population.

Cell Cycle Analysis: Determining the distribution of cells in different phases of the cell cycle.

Apoptosis Detection: Assessing cell death and apoptosis using markers like Annexin V and propidium iodide.

Intracellular Protein Analysis: Analyzing protein expression within cells using antibodies and permeabilization methods.

Cell Sorting: Separating specific cell populations based on defined criteria using high-speed droplet-based sorting.
